# Cloud Native Applications Project

## Architecting a Cloud-Native Application using GitOps and Serverless

---

Katsimpras Drosos (ais25123)

Harokopio University of Athens

Department of Informatics and Telematics

MSc in Advances in Computer Science and Informatics Systems

Supervisors: Dr. Kousiouris Georgios | Dr. Tsadimas Anargyros | Academic Year: 2025-2026

# Table of Contents

1. Introduction
2. Proposed Architecture & Methodology
3. Automation & Security
4. GitOps & CI/CD
5. Design Patterns & Resilience
6. Serverless Computation
7. Monitoring, Scaling & SLAs
8. Conclusions & Future Work

## Introduction

---

*The application was already containerized (Docker) and running in MicroK8s – but locally.*

## Tied Infrastructure

No independent scaling or remote access.

## Manual Configuration

Non-reproducible environment, step-by-step setup.

## Manual Deployments

Every code change = manual rebuild/redeploy.

## No Secrets Management

Hardcoded credentials, no proper monitoring.

## Objective of the Project

Transition to a fully automated, **cloud-native infrastructure on Azure** — without changing the application's underlying business logic.

## *Transforming a local prototype into a resilient cloud-native platform*

### Multiple Cloud Tech

Each selected for a specific functional role

### Resilience Patterns

Claim Check, Retry, Idempotency, Stateless

### Serverless Computing

Event-driven logic without permanent compute

### Infrastructure as Code

Full automation via OpenTofu & Ansible

### GitOps Practices

Jenkins (CI) + ArgoCD (CD), zero manual steps

### Documented SLAs

Based on real load testing measurements

## Proposed Architecture & Methodology

---

# THE EVOLUTION: CURRENT VS TARGET STATE

## *Orchestrated microservices and the Claim Check pattern*

### Core Design Decision — Claim Check & Persistent Volumes (PVC):

Images are saved directly to **MinIO**. Only a lightweight URL-reference is passed to **RabbitMQ** — not the file itself. Saving to **MinIO** acts as a trigger for the serverless thumbnail generation. Furthermore, **PVCs** decouple storage from pods, ensuring data survives restarts.

## Automation & Security

---

## OpenTofu — The “Shell”

- ✓ Declarative definition of Azure resources in version-controlled files.
- ✓ Resource group → VNet/Subnet → NSG → NIC → Linux VM.
- ✓ Ubuntu server without UI
- ✓ Access only via SSH key — no password.
- ✓ Auto-shutdown at 23:00 (FinOps practice).

9 resources · \$133.03/month cost estimate (Infracost)

## Ansible — The “Inside”

*base-setup*

*vault*

*monitoring*

*jenkins*

*argocd*

*knative*

*infracost*

7 independent, **idempotent roles** — safe re-execution after every deallocate/start of the VM, without distinguishing the “first time”.

**idempotent tasks:** “check if exists” → install only when missing

# SECRETS MANAGEMENT WITH HASHICORP VAULT

*Centralized, secure storage of credentials — no hardcoded values in Git.*

- ✓ **Kubernetes auth method** — each pod authenticates via its service account, not a static token.
- ✓ **Shamir seal** — file storage protected with an unseal key.
- ✓ **Fallback to environment variables** if Vault is unavailable (e.g., local development).

## GitOps & CI/CD

---

# GITOPS: THE END-TO-END PIPELINE

## 🔍 Selective Execution (Jenkins)

Monorepo + `when { changeset }` → build only when the component changes. No redundant images built.

## ∞ Self-Heal + Prune (ArgoCD)

Git is the single source of truth. Manual `kubectl` edits are automatically reverted. Resources not in Git are pruned.

## Design Patterns & Resilience

---

## Claim Check

Large files → MinIO. Only the URL reference travels, keeping message payloads lightweight.

## Retry

3 connection attempts with a 2s fixed delay to gracefully handle transient network hiccups.

## Idempotency

Client-side key ensures safety. Subsequent requests with the same key → **409 Conflict**.

## Stateless

No local session state. Independent instances scale easily using JWT + MongoDB persistence.

## 1st Request

`POST /api/products`  
`-F "idempotencyKey=demo-12345"`

**201 Created**

## 2nd Request (same key)

`POST /api/products`  
`-F "idempotencyKey=demo-12345"`

**409 Conflict**

*"Duplicate request - already submitted"*

**Unit Test Coverage:** Verified 3 scenarios: new key, reused key, and request without key.

**Scenario:** Network retry or accidental double-submit sends the *same* request twice — without a key, the backend has no way to detect this.

The screenshot shows the MinIO web interface for a bucket named 'products'. The breadcrumb path is 'products / img-1781714833429-levis.jpeg'. A table lists three files, all of which are identical copies of the same image, uploaded at the same time (Today, 19:47) and with the same size (19.8 KiB).

| <input type="checkbox"/> | Name                                                                                                           | Last Modified | Size     |
|--------------------------|----------------------------------------------------------------------------------------------------------------|---------------|----------|
| <input type="checkbox"/> |  img-1781714833429-levis.jpeg | Today, 19:47  | 19.8 KiB |
| <input type="checkbox"/> |  img-1781714833567-levis.jpeg | Today, 19:47  | 19.8 KiB |
| <input type="checkbox"/> |  img-1781714833592-levis.jpeg | Today, 19:47  | 19.8 KiB |

**Result:** Three identical uploads (*img-...429, ...567, ...592*) land in MinIO within seconds — duplicate data with no protection at the API layer.

**Scenario:** Same request, same *idempotencyKey*, sent twice — this time the backend remembers.

```
azureuser@fabric-vm:~/fabric-smart-warehouse$ KEY="demo-recording-fixed-001"
curl -i -X POST http://localhost:32764/api/products \
  -F "idempotencyKey=$KEY" \
  -F "name=Test Product" \
  -F "image=@test2.jpg"

# RETRY PATTERN: IMPLEMENTATION

## Generic Retry Utility (retry.js)

```
async function retryWithDelay(fn, { retries = 3, delayMs = 2000,  
                                  label = "operation" } = {}) {  
  for (let attempt = 1; attempt <= retries; attempt++) {  
    try {  
      return await fn();  
    } catch (err) {  
      if (attempt < retries) {  
        await new Promise((resolve) => setTimeout(resolve, delayMs));  
      } else {  
        throw err;  
      }  
    }  
  }  
}
```

## Applied to: MongoDB Connection (Startup)

```
retryWithDelay(  
  () => mongoose.connect(MONGO_URI)  
    .then(() => console.log("MongoDB connected")),  
  { retries: 3, delayMs: 2000, label: "MongoDB connection" }  
);
```

## Serverless Computation

---

## Why Knative?

- Runs on existing MicroK8s (no extra infra)
- No vendor lock-in (vs AWS Lambda)
- Scale-to-zero: zero idle resource usage
- Cold start on new events

## Triggering Mechanism

1. New file in MinIO bucket
2. MinIO event notification (webhook)
3. Knative function triggered
4. *sharp*: `resize 200 × 200` → *thumb*- prefix

**Note:** Same design philosophy as the resilience patterns chapter — independent scaling, no permanently reserved resources.

# DIAGNOSIS: INFINITE LOOP IN EVENT-DRIVEN LOGIC

*The fix (checks both possible formats):*

```
if (tags.some(t => t.Key === 'processed' &&  
    (t.Value === 'true' || t.Value === true)))
```

## Monitoring, Scaling & SLAs

---

## Prometheus + Grafana

CPU & memory per pod, HTTP request count. Custom dashboard for backend + Vault Agent sidecar, plus "Node Exporter Full".

Node-level utilization (24h)

9.4%

CPU

49.9%

Memory

31.7%

Disk

*Despite co-hosting Jenkins, ArgoCD, Vault & app.*

## Pod Autoscaler (HPA)

Two independent reference metrics — the higher result between them is adopted:

CPU target 50%

Memory target 70%

min / max replicas 1 → 5

*Operates reliably because the backend is stateless — every new replica serves requests immediately.*

## Grafana: CPU and Memory Usage of the Backend Pod

## Grafana: Node Exporter Full Dashboard

## GET /api/products

100 virtual users · 6,823 requests

**14.2ms**

p(95)

0.00%  
failure rate

## POST /api/products

20 virtual users · 1,018 requests

**80.1ms**

p(95)

0.00%  
failure rate

### Gold SLA

< 100ms

GET endpoints (measured 14.2ms)

### Silver SLA

< 250ms

POST endpoints (measured 80.1ms)

### Bronze SLA

< 500ms

Worst-case, all requests

## Conclusions & Future Work

---

## Conclusions

- **Cloud-native transformation:** Automated, observable, GitOps-driven platform on Azure.
- **Full GitOps automation:** `git push` flows seamlessly to the cluster via Jenkins & ArgoCD.
- **Resilience by design:** Claim Check, Retry, Idempotency and Stateless patterns.
- **Key Takeaway:** Complexity lives in the *interactions* between technologies, not in isolation.

## Known Limitations & Future Work

- **Circuit Breaker:** Not yet implemented (a natural extension to the Retry mechanism).
- **RabbitMQ secrets:** Connection relies on env variables due to a known Docker image limitation.
- **GET pagination:** `/api/products` returns all records (degrades performance under high load).
- **Pod-level FinOps:** Requires additional tooling (e.g., *OpenCost*) beyond *Infracost*.
